

Broaches re-sharpening

When the cutting edge has a radius of 0,02 – 0,05 mm the roughness of the machined surface is very bad and also the force required is around 30% higher.

If we regrade the broach when the wear is to this level it's necessary to remove only 0,06 – 0,08 mm, but if we wait that the wear increases a lot, we need to remove more material, for example 0,3 - 0,5 mm, with a shorter life of the broach.

The roughness must be around $R_a = 0,2 \mu m$.

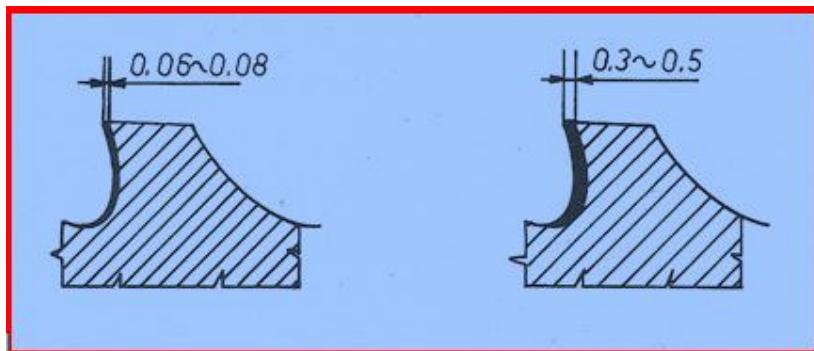

Fig. N°1

If the axis of the broach and the axis of the wheel are in the same plane, the wheel touch the face of the broach in two points.

In this case the marks of grinding wheel in the face have two direction and in the cutting edge is preset a lot of burrs.

On the contrary, if the axis of the grinding wheel is displaced out of the plan of the workpiece, the grinding wheel touch the face only in one point, the marks have one direction and the burr is smaller. (See fig. N°2).

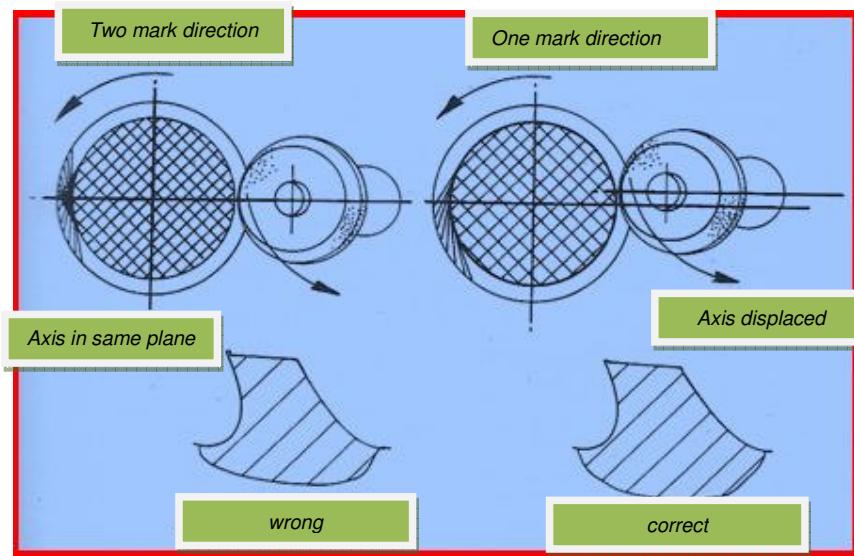

Fig. N°2

Fig.N°3- Resharpening of a broach of Sib Sideral- (Leini- Torino – Italy)

The most important point is to set correctly grinding wheel diameter and inclination angle of the wheel in order to obtain a correct rake angle.

The above two values are depending also of broach diameter.

It's valid the following formula.

$$D = 0,85 \cdot d \cdot \frac{\sin(\beta - \gamma)}{\sin \gamma}$$

Where:

D = grinding wheel diameter

d = outside diameter of the broach

β = grinding wheel inclination

γ = rake angle

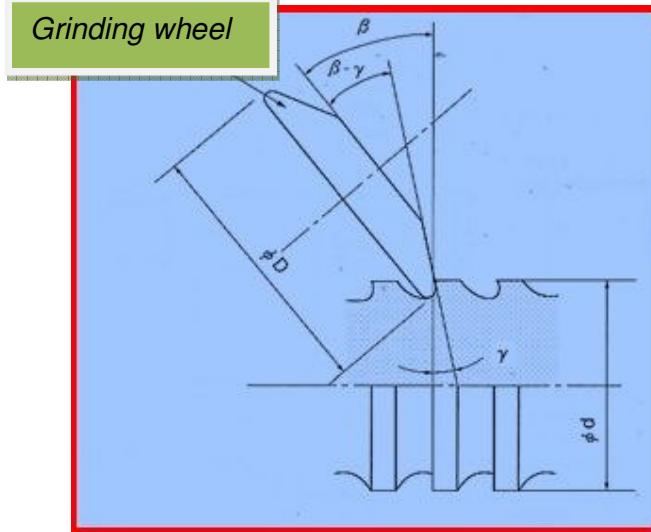

Fig. N°4

In the followings two tables are show the diameters of grinding wheel in according to the other parameters.

Table N°1 - Diameter of grinding wheel for round broaches

Broach Diameter <i>d</i>	Grinding wheel inclination $\beta=30^\circ$							Grinding wheel inclination $\beta=40^\circ$						
	Rake angle γ							Rake angle γ
